## AMMONIA IR ABSORBANCE MEASUREMENTS WITH AN EQUILIBRIUM VAPOR CELL

#### INTRODUCTION

This report furnishes the ammonia infrared (IR) absorbance spectra that are derived from fifteen gravimetrically prepared and three commercial aqueous ammonia solutions. Background vapor phase absorbance spectra were collected using pure water to provide a zero ammonia concentration reference. Previous studies using this dynamic vapor liquid equilibrium technique to maintain controlled vapor concentration were made on aqueous volatile organic compound (VOC) solutions for vapor generation in IR absorbance measurements.<sup>1</sup>

The ammonia vapor IR absorbance spectra and water vapor absorbance spectra are obtained from IR interferogram data by monitoring the contents of the dynamic equilibrium vapor cell (EVC) with a traditional bench Fourier transform infrared (FT-IR) spectrometer. The equilibrium vapor cell partial pressures are determined by the concentration of ammonia solute in the circulating nitrogen gas bubbled through the aqueous solution in the EVC configuration.<sup>2</sup> A plot of absorbance versus the EVC generated ammonia vapor mole fraction is found to be linear for all but the three highest concentrations (>4 mole % liquid ~ 2.2 M ~ 25 torr) of the eighteen solutions.

#### EXPERIMENTAL METHODS

A detailed description of the EVC method for controlled generation of partial vapor pressures has been previously reported.<sup>2</sup> Specifics of the prepared solutions including the sample identifier numbers, solvent and solute net weights, and computed mole percentages are furnished in Table 1 along with dates of preparation. The total solution weights range from 141 to 163 g (approximate 30 g tare weight) and are within the 200 g capacity of the single pan analytical balance having a precision of 0.1 mg employed (Model AE200; Mettler Instruments Corporation, Highstown, NJ). Distilled and deionized water was used as solvent in the solution preparation. The anhydrous ammonia (Matheson Gas Products Incorporated, Montgomeryville, PA) was obtained from a pressure regulated lecture bottle. Ammonia is bubbled through a capillary pipette into the tared and weighed water solvent. Ammonia weight gain is monitored to a predetermined amount and weighed with the pipette removed. Mole fractions were calculated using molecular weights of 17.03 and 18.02 for the solute and solvent respectively.

In addition to the prepared aqueous solutions in Table 1, three commercial solutions were examined. Their sources and specified concentrations are listed in Table 2. The mole percent fractions (i.e., X% and Y%) in Table 2 and Table 3 are determined using Wilson coefficients for the two aqueous ammonia solutions computed with the program MOLARFRC.BAS listed in Appendix A using the molarity specified by

the suppliers.<sup>3</sup> The third solution (5% V/V) was determined from the Beer's Law (absorbance versus concentration) plots of the other solutions as described below (see Appendix B).

Acquisition of interferogram data with the FT-IR spectrometer (Model M2004, Serial Number 514; Midac Corporation, Irvine, CA) employed the MDGRAMS32 application software package (Galactic Industries Corporation, Salem, NH). The interferogram data was transformed with the MDGRAMS software into single-beam spectra at a nominal 0.5 cm<sup>-1</sup> spectral point spacing. The single-beam spectra were subsequently used to compute the IR absorbance spectra tabulated in Appendixes C, D, and E for prepared ammonia, purchased ammonia, and pure water solutions, respectively. Replicate spectral measurements noted in Table 3 permitted computation of multiple IR absorbance values at each solution concentration. These absorbance values were used to evaluate an average absorbance and its standard deviation. The filenames and associated calculated ammonia liquid mole percentage are listed in Table 3.

The IR cell pathlength was determined using a horizontal cathetometer in a caliper configuration to measure the outside dimensions of the assembled cell. The lengths obtained from six consecutive determinations (see Table 4) gave a mean of 10.21 cm with an average deviation of 0.04 cm. Because the cell used 6.0 mm thick windows, the computed internal cell pathlength is taken to be 9.01 cm.

#### IR ABSORBANCE

Calculation of the IR absorbance spectra requires taking the ratio of single-beam sample to blank spectrum for ammonia concentration to determine the transmittance spectrum. The transmittance spectrum is converted to IR absorbance spectrum by taking the base ten logarithm of the reciprocal of the transmittance. Ten IR absorbance spectra are available for each ammonia concentration (see Table 3). However, in three cases, the vapor cell had not equilibrated so fewer than ten replicates (i.e., N) are available. The absorbance spectra for each target analyte concentration are summed and subsequently divided by the number (i.e., N) of spectra to produce an average spectrum (i.e., AVE). Using the average absorbance, the average deviation is computed for each ammonia concentration shown in Table 3. The average deviation (AD) for the spectral region from 750 cm<sup>-1</sup> to 1200 cm<sup>-1</sup> is computed at each 0.5 cm<sup>-1</sup> wavenumber spacing with equation 1.

$$AD = \sum |AVE-ABS(i)|/N$$
 (1)

The AVE represents the average absorbance spectral value at a specific wavenumber; ABS(i) denotes one of N absorbance spectrum samples at a particular wavenumber; and N indicates the number of absorbance spectra used in determining the average (usually ten). Figure 1 shows a plot of average absorbance spectra for the prepared and commercial solutions over the spectral range from 920 cm<sup>-1</sup> to 980 cm<sup>-1</sup>. Figure 1a illustrates the prepared solutions ordered as listed in Table 5 from the smallest concentration of X% of 0.00 and Y% of 0.00 to the largest concentration of X% of 6.42 and Y% of 71.1. Figure 1b displays the three commercial solutions with concentrations listed as entries 3, 9, and 20 in Table 5. The LV (5% V/V) has the largest concentration and absorbance that is shown in Figure 1b. The concentrations for the LV solution listed in Table 5 are determined from IR absorbance measurements.

a Normality

Peak absorbance values for select IR bands of ammonia are listed in Table 6. These values are obtained after eight times zero filling the original interferograms before Fourier transforming into single-beam spectra and subsequent computation of absorbance. Band locations of five major peaks are presented in Table 6. The average absorbance values of these five major peaks are given along with the associated uncertainty (i.e., average deviation). The program NH3ABC.BAS is used to compute the least squares plots of absorbance versus either ammonia Y% mole fraction or vapor pressure. This program is listed in Appendix A. The computational results of this program are furnished in Appendix B for the derived absorbance spectra without zero filling of the interferograms.

<sup>&</sup>lt;sup>b</sup> Determined from IR absorbance measurements without interferogram zero filling.

The results of both with and without zero filled interferograms are summarized in Table 7. Tables 7a and 7b are linear least squares results from absorbance versus Y% mole fraction of the ammonia vapor. Table 7a presents the least squares results when no zero filling is used. The lowest 16 concentrations that are listed in Table 5 are used in generating the Table 7a results. Table 7b tabulates the least squares results when using eight times zero filling. The linear region varied from the first 12 to 16 concentrations as denoted under the column labeled "Pts." in Table 7b. Each of the absorbance versus Y% mole ammonia vapor fraction least squares analyses allows a prediction of the 5% V/V solution as given in entry 20 of Table 5. The predicted Y% from Table 7a is 28.63±0.65, whereas from Table 7b is 28.32±0.50. These Y% values lie within each other's uncertainty range.

Tables 7c and 7d are linear least squares results from absorbance versus ammonia vapor pressure. Table 7c presents the least squares results without zero filling. Table 7d tabulates the least squares results when using eight times zero filling. The linear region for the absorbance versus ammonia vapor pressure is over the first 12 concentrations in Table 5. The predicted ammonia vapor pressure for the 5% V/V solution from Table 7c is 6.90±0.08 Torr, whereas for Table 7d the predicted 5% V/V solution ammonia vapor pressure is 6.82±0.10.

Similar to the mole fractions in Tables 7a and 7b, the predicted ammonia vapor pressures derived from Tables 7c and 7d are nearly identical. The liquid mole fractions (X%) and molarities (M) associated with the vapor concentrations (either Y% or P) also display small differences because of the variation in temperature of the EVC between solutions. As shown in Table 5, most solutions clustered either around 20.5 or 21.5 °C. These differences in X% and M, due to the temperature variation for either Y% or P, are slightly less than 3%. More significant differences in liquid concentrations that are predicted by Y% compared to that of P are slightly greater than 6%. Table 8 provides a tabulated comparison of both the temperature and concentraton prediction (see Table 7) difference.

The least squares results for the Table 6 absorbance values derived from zero filled interferogram data are shown in Figure 2. The solid lines are the least squares lines (see slope and intercept values of Tables 7b and 7d). The symbols representing each peak absorbance are as follows: down solid triangle, 908.04 cm<sup>-1</sup>: down open triangle, 930.70 cm<sup>-1</sup>; up open triangle, 966.74 cm<sup>-1</sup>; solid diamond, 992.41 cm<sup>-1</sup>; and open diamond, 1026.80 cm<sup>-1</sup>. Figure 2a is a plot of absorbance versus ammonia vapor mole fraction (i.e., A versus Y), whereas Figure 2b is a plot of absorbance versus ammonia vapor pressure (i.e., A versus P). The A versus Y plot exhibits linearity for the 1026.80 cm<sup>-1</sup> peak absorbance up to about 0.5 mole fraction that encompasses all but three of the solutions listed in Table 5. On the other hand, the A versus P plot exhibits linearity for the 1026.80 cm<sup>-1</sup> peak absorbance up to only about 7 Torr that includes only the first 12 concentrations of Table 5 as shown in Figure 2c. Clearly, use of A versus Y furnishes a more robust linear fit of the absorbance data. The output results of the NH3ABC.BAS program for the absorbance data in Appendixes C. D. and E without zero filling of interferograms are both tabulated and plotted in Appendix B.

Zero filling of the interferogram does not furnish any additional spectral resolution in the absorbance spectrum, however it does provide the best statistical means of interpolating between sampled points across the entire spectrum.<sup>5</sup> This interpolation by means of zero filling offers a means of more accurately establishing the true peak absorbance if the spectral bands are under sampled. Figure 3 shows the five absorbance curves for ammonia vapor generated with entry 6 of Table 6 (i.e., X% = 0.683 and Y% = 16.4). The absorbance curves associated with and without zero filling of the five peak absorbance values in Table 6 are plotted in Figure 3. Open circles are zero filled interpolated values and solid circles are the values without zero filling. Figures 3a, 3b, 3c, 3d, and 3e are the curves for absorbance peak values of 908.04 cm<sup>-1</sup>, 930.70 cm<sup>-1</sup>, 966.74 cm<sup>-1</sup>, 992.41 cm<sup>-1</sup>, and 1026.80 cm<sup>-1</sup>, respectively. In all but one case without zero filling, the peak value does not coincide with the peak interpolated value. The peak value with and without zero filling coincides for the 1026.8 cm<sup>-1</sup> spectral wavenumber shown in Figure 3e. This sampling of the peak value undoubtedly results in the 1026.8 cm<sup>-1</sup> exhibiting the best linearity of the five bands in for the A versus Y plots of Figure 2 and Appendix B.

#### 4. DISCUSSION

The ammonia vapor pressures that are generated by the aqueous ammonia solutions are temperature dependent. Table 5 lists the solution temperatures in the fourth column. For the vapor pressure data of Scheffer and DeWijs at 25 °C, the ammonia partial pressure in units of Torr as a function of molality m (i.e., as opposed to molarity M) is found to provide an excellent empirical fit.<sup>3,6</sup> The coefficients of the equation 2 empirical fit are A, -2.04×10<sup>-3</sup>; B, 12.75591; and C, 0.3937456.

$$P_{\text{vap}} = A + B \times m + C \times m^2$$
 (2)

A more generalized temperature dependent fit employing Wilson coefficients of all available aqueous ammonia vapor liquid equilibria data permits broader application.<sup>3</sup> Table 9 lists the potential effect of temperature on the 5% V/V solution. Table 9 is generated with the MOLARFRC.BAS program listed in Appendix A. The molarity values in Table 9 include the range of values provided by the supplier (see Table 2 footnote e). The ammonia vapor pressure values at 20.5 °C (see Table 5 entry 20) differ from the IR measurement values by only about 5 to 7% (i.e., 0.37 to 0.50 Torr).

This study relies on gravimetric preparation of the solutions for determining the amount of ammonia in aqueous solution. As an additional verification of this approach, two prepared solution ammonia concentrations were compared by titration using the following procedures with the stated results.

A 1.0 N standard solution of sodium hydroxide (NaOH) was prepared and standardized against weighted quantities of potassium acid phthalate (KHP mol. wt. 204.228). Three samples (8.225 g, 8.1381 g, 7.4466 g) titrated respectively with the NaOH solution aliquots of 42.83 mL, 41.81 mL, 38.86 mL using a phenolphthalein indicator to yield normalities of 0.9404, 0.9530 and 0.9383 for an average of 0.9439 ± 0.0061 for the NaOH standard solution. A 1.0 N hydrochloric acid (HCI) solution was prepared and standardized against the NaOH standard. Samples of the HCI (40.18 mL, 39.94 mL, 40.22 mL) were titrated respectively with NaOH aliquots of 37.39 mL, 36.91 mL, 37.44 mL using a phenolphthalein indicator to yield normalities of 0.8784, 0.8723, and 0.8787 for an average of 0.8772 ± 0.0033 N.

Two gravimetrically prepared solutions were titrated against the HCI standardized solution using methyl red indicator. The first prepared solution originally prepared on 12/11/00 consisted of 146.1487 g of water and 0.7646 g of ammonia Ibracketed by entries 5 (#8) and 6 (#12) of Table 5]. Titration of this 0.550 mole % solution yielded values of 0.3012M and 0.2992M. A second solution prepared on 3/28/03 was composed of 141.8345 g of water and 0.7305 g of ammonia. Titration of this 0.542 mole % solution resulted in values of 0.2935M and 0.2934M. These two solutions differed by less than 3% in molarity and mole percent. Storage of the 147 g solution in a 250 mL capped polypropylene (Nalgene) bottle for a period of more than two years did not significantly effect the ammonia solution concentration. The MOLARFRC.BAS program listed in Appendix A using the titration molarities and input temperature of 25 °C gave 0.544 mole % for the 12/11/00 solution and 0.532 mole % for the 3/28/03 solution. The difference in these mole percent values from the gravimetric values of about 1 and 2%, respectively, was considered to be insignificant. Titrimetric analysis for determination of ammonia concentration of the gravimetrically prepared ammonia solutions was not deemed necessary.

#### SUMMARY

Infrared (IR) absorbance data for aqueous ammonia solutions are acquired using the equilibrium vapor cell method. This data is presented in the form of average and average deviation files that are compiled in a set of appendixes. The experimental conditions of solute and solvent weights for gravimetrically generated ammonia vapor concentrations are reported, as well as the equilibrium vapor cell pathlength. Prepared and commercially procured aqueous solutions were used in this study.

The IR evaluations using absorbance versus ammonia mole fraction (i.e., A versus Y) or vapor pressure (i.e., A versus P) showed excellent agreement with the specifications for both the prepared and commercial solutions. The plotting of A versus Y provided a more robust description for the absorbance data than the more traditional A versus P type of approach. The use of zero filling of interferograms proved to be an effective means of acquiring the maximum absorbance values for the five narrow ammonia spectral bands that were examined in this study.
